

# GRBs, Dust, and the High-Redshift Universe

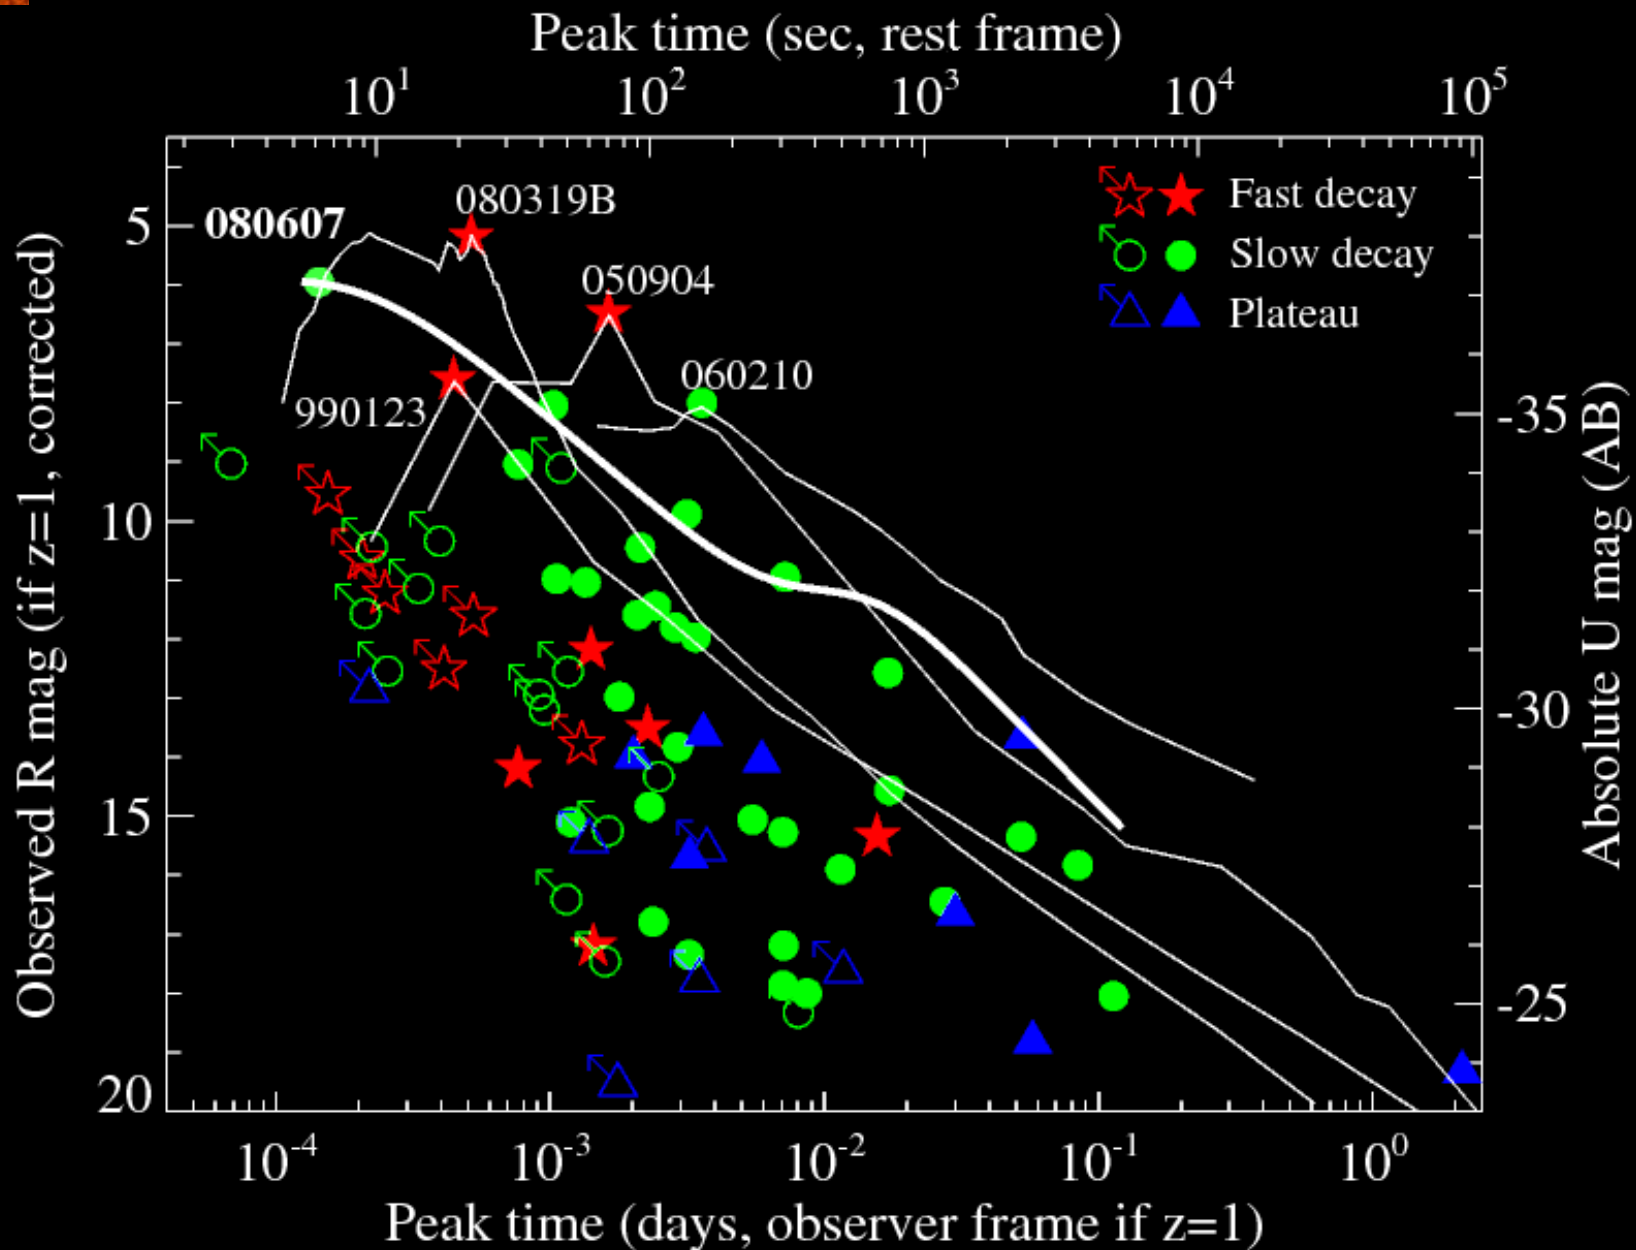

The background of the slide is a rich, multi-colored nebula or galaxy core. It features a central bright blue and white jet-like structure that extends upwards and downwards. The surrounding regions are a mix of orange, red, and blue, with numerous small white stars scattered throughout the field.

(Hubble Fellow, Caltech)

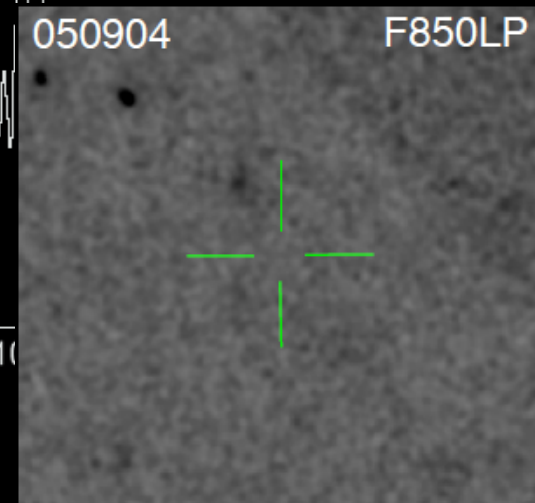

# GRBs: Massive Stellar Core Collapse

# Extremely Luminous Transients

## GRB 050904 ( $z=6.295$ )

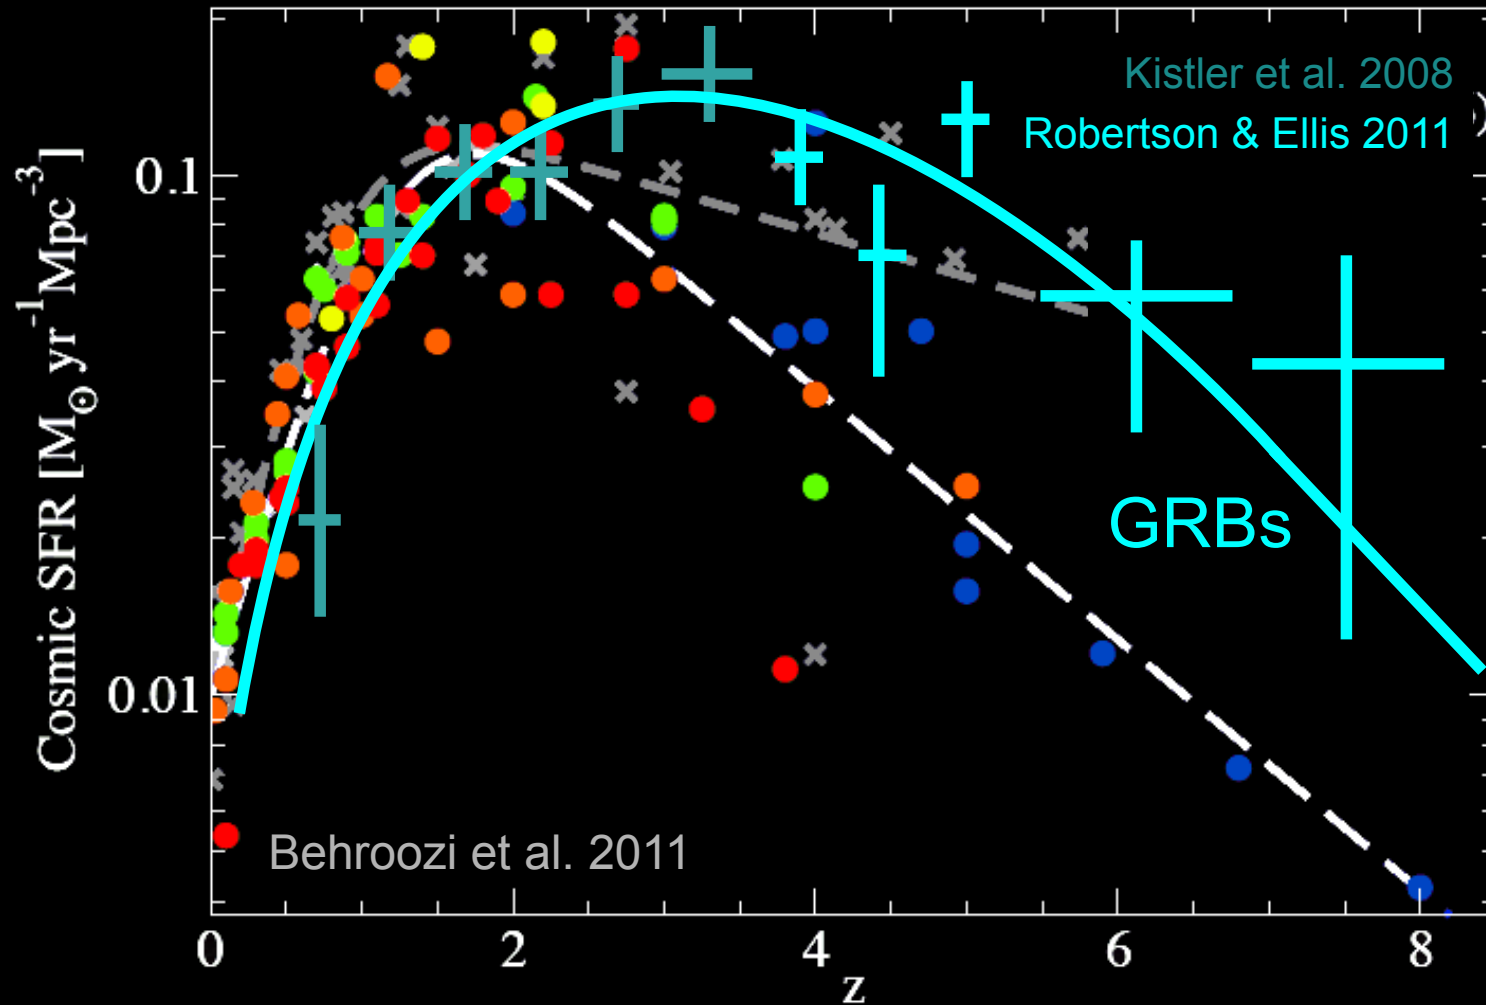

Kawai+2006

# GRB Populations as SFR Tracers

# GRB Populations as SFR Tracers

# GRB hosts vs. SN hosts

GRB host galaxies (irregular, young)

SN host galaxies (spiral, mature)

Fruchter+ 2006

# Heavily Obscured GRB 080607

~25% of GRBs are **dark**:

No optical afterglow,  
even with early follow-up. →

- Can't identify host without X-ray or radio follow-up.
- Can't measure redshift without large ground-based telescopes.

Palomar 60-inch follow-up of GRB 061222A  
~10 minutes after burst

# Hosts of Dust-Obscured GRBs

# GRB hosts vs. Field Galaxies

GRBs sample “all” types of star-forming galaxies, and dusty  
GRBs prefer dustier, more massive, more star-forming hosts...

“ordinary” mildly  
obscured GRBs

heavily obscured  
GRBs

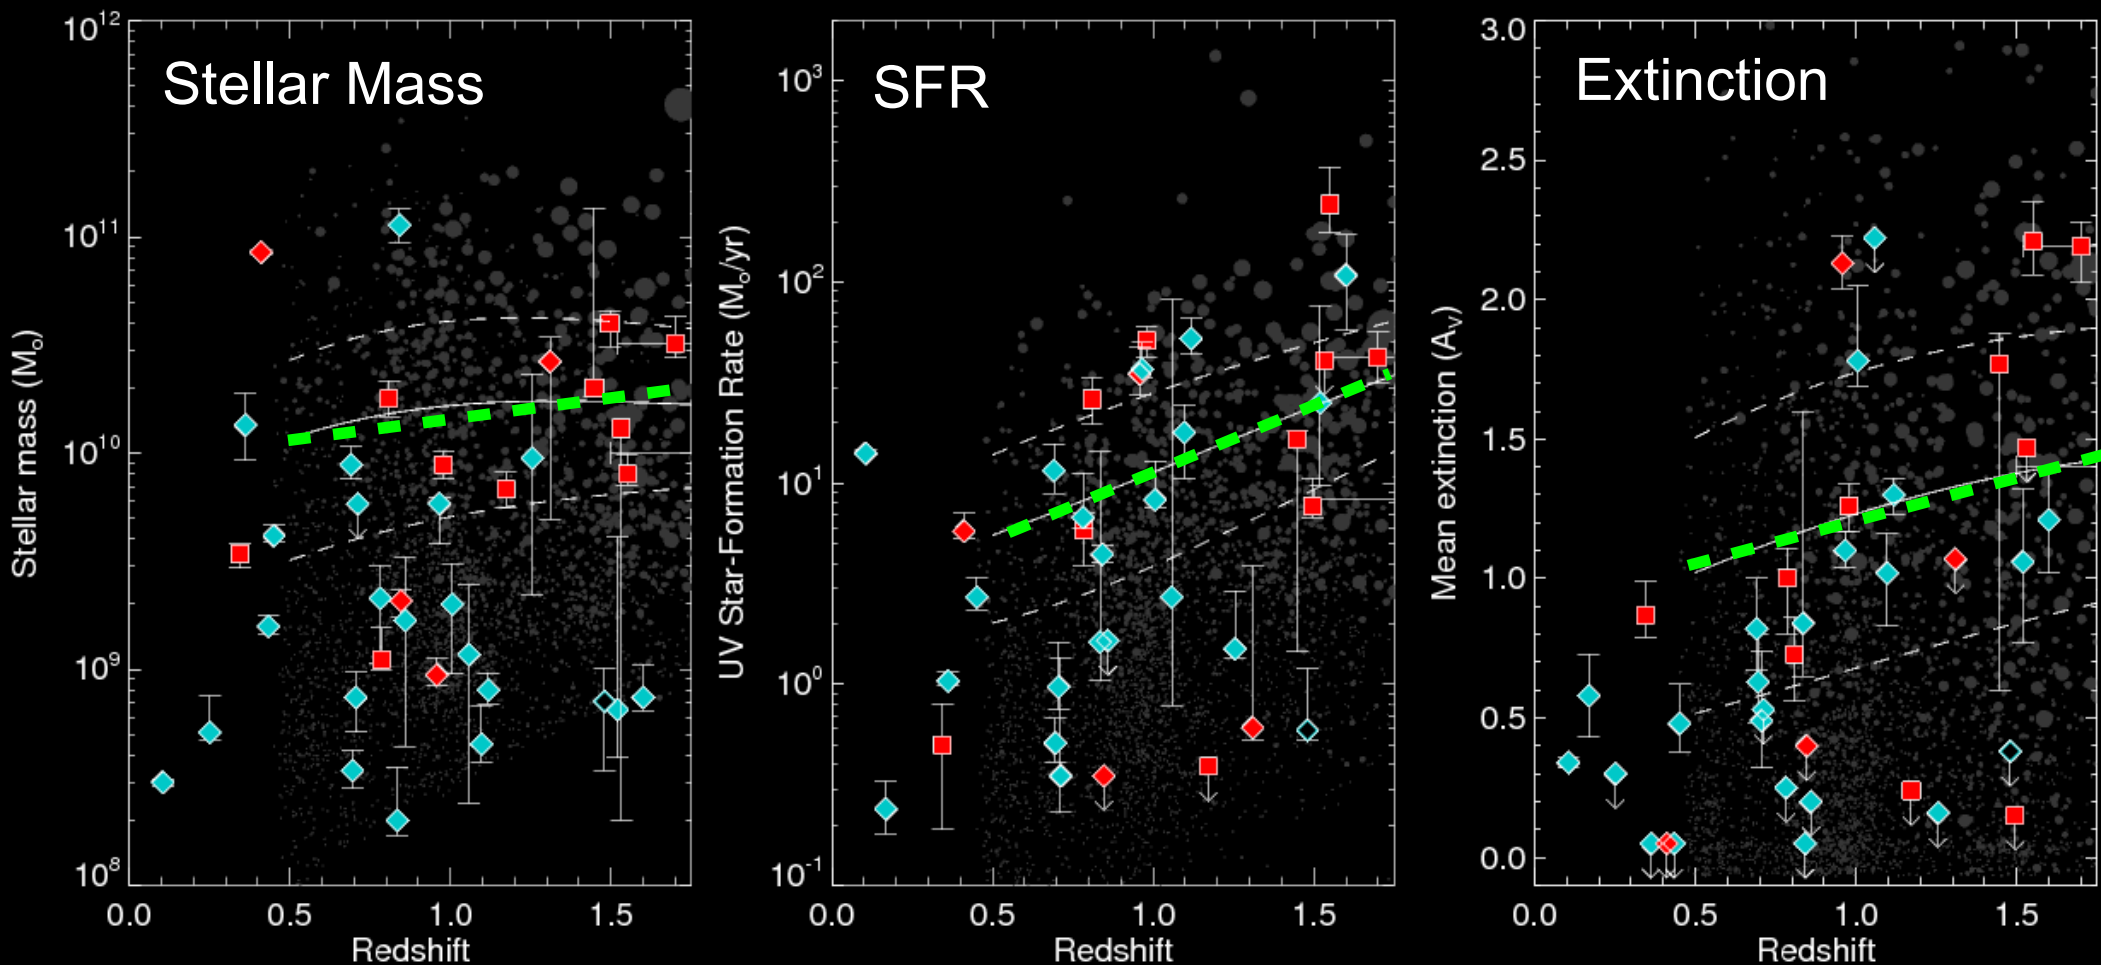

Grey points: K-selected field galaxies  
(Kajisawa et al. 2011)

# GRB hosts vs. Field Galaxies

GRBs overall still strongly trend towards low-mass, low-dust, high-sSFR systems.

*expected population median as a function of redshift for a uniform SFR-tracer*

# Moving to Higher Redshifts

Improvement at higher redshifts, but a preference for the faintest and bluest galaxies persists.

(Consistent with metallicity evolution?)

Understanding the deviation: metallicity or something else?

Constraints on the progenitor?

Can we correct GRB rates → SFR calibrations?

Effects of *types* of dust. (Origin of 2175 Angstrom absorption feature?)

Multiwavelength view: abundance of submillimeter hosts

Links to other extreme transients (luminous SNe)
